Novel 1,3-dichalcogeno-2-phospholanes with an annelated 1,2-dicarba-closo-dodecaborane(12) Unit

By Bernd Wrackmeyer*  
Elena V. Klimkina†  
Wolfgang Milius‡

The most efficient strategies for the synthesis of novel 1,3-dichalcogeno-2-phospholanes (chalcogen E = O, S, Se, Te) are introduced, starting from 1,2-dicarba-closo-dodecaborane(12) ("ortho-carborane"), its 1,2-di-lithiated derivative, and various phosphorus halides. The annelation of the phospholane ring with the rigid three-dimensional carborane framework causes markedly different properties when compared with other phospholanes. Most noteworthy are the structural alternatives concerning the orientation of the lone pair of electrons at phosphorus, the instability of P-halides in particular for E = O, and the pronounced tendency for dimerization in the case of P-organo derivatives, which increases from E = Te < Se < S << O. The latter is a consequence of spatial proximity between P-R or electron density at phosphorus and the carborane skeleton. Direct structural evidence is provided for monomers and dimers by single crystal X-ray structural analysis. The solution-state structures follow from consistent sets of multinuclear magnetic resonance data (1H, 11B, 13C, 31P, 77Se, 125Te NMR). This is complemented by calculations leading to optimized gas-phase geometries at the B3LYP/6-311+G(d,p) level of theory. Most NMR parameters (chemical shifts δ and indirect nuclear spin-spin coupling constants 1J) are calculated at the same level of theory. These studies indicate that there are cases, for which important features of the solid-state structures may not be retained in solution.

Introduction

1,3-Dichalcogeno-2-phospholanes have been known for some time, in particular the 1,3-dioxo- (Arbuzov, 1948; Lucas, 1950; Burg, 1961; Fontal, 1966) and less so the 1,3-dithia derivatives (Arbuzov, 1952; Wieber, 1964; Peake, 1972; Albrand, 1973), by contrast to rare examples for 1,3-diselena-

doi=10.30958/ajs.1-2-1
(Ogawa, 1995) and non-existent 1,3-ditellura compounds. These cyclic phosphines differ in many respects from their six-membered or non-cyclic counterparts. The carbon backbone frequently consists of the CH₂-CH₂ moiety (A) or is a benzo group (B). The typical structures, of which many have been determined by X-ray analysis, are presented in Fig. 1. Usually one finds an envelope structure with the phosphorus atom in the flap and the substituent at phosphorus in the axial position, leaving the equatorial space for the lone pair of electrons. In the solid state, the CH₂ units may be arranged as in A or twisted against each other (A'), to escape the maximum of steric repulsion exerted by the substituent at phosphorus. The latter alternative is unnecessary in the case of the benzo derivatives (B). A rigid three-dimensional unit instead of the CH₂-CH₂- or the benzo group could change the principal structure (see D as compared with C) and by this the properties of such compounds. Therefore, we have set out to synthesize and investigate 1,3-dichalcogeno-2-phospholanes with an annelated 1,2-dicarba-closo-dodecaborane(12) unit (C and/or D).

Figure 1. Principal structures of 1,3-dichalcogeno-2-phospholanes (E = O, S, Se, Te)

![Figure 1](image)

The chemistry of 1,2-dicarba-closo-dodecaborane(12) 1 (so called "ortho-carborane") in general is well developed (Grimes, 2011; Bregadze, 1992). One important step for derivatization involves di-lithiation (2), and for our purposes, insertion of sulfur (Smith, 1966; Herberhold, 1999; Popescu, 2012), selenium (Herberhold, 1999; Jin, 2004) or tellurium (Herberhold, 1999; Wrackmeyer, 2013, 398-408) into the C–Li bonds (3). The oxygen derivatives 4 (Ohta, 2007) and 5 have to be prepared by a different route, and the silanes 6 (Wrackmeyer, 2010; Wrackmeyer, 2014, Dalton Trans.) turned out to be particularly useful for further transformations. Scheme 1 shows the information on starting materials which can be used in reactions with phosphorus halides to obtain the desired novel 1,3-dichalcogeno-2-phospholanes.

NMR spectroscopy (¹H, ¹³C, ¹¹B, ²⁹Si, ³¹P, ⁷⁷Se and ¹²⁵Te NMR) is the major analytical tool for the assessment of solution-state structures. These measurements are accompanied by quantum-chemical analyses aiming for optimization [B3LYP/6-311+G(d,p) level of theory (Becke, 1993; Lee, 1988, Stevens, 1994, McLean, 1980; Krishnan, 1980)] of gas-phase structures and calculation of NMR parameters [chemical shifts δX (X = ¹¹B, ¹³C, ³¹P, ⁹⁹Se) (Wollinski, 1990) and indirect nuclear spin-spin coupling constants ¹J(A,X) (Helgaker, 2008; Contreras, 2003)].

Results & Discussion

1,3-Dioxa-2-phospholanes with an annelated 1,2-dicarba-closo-dodecaborane(12) Unit

Scheme 2 shows that the phosphorus halides 7 are formed as expected. However, after short time in the reaction solutions or in the course of work-up procedures disproportionation reactions towards phosphite derivatives 8 take place (Wrackmeyer, 2014, 233-246). Apparently, the phosphorus halides 7 are less stable than comparable halides of the type A or B (E = O; Fig. 1) some of which are commercially available. So far neither the parent phosphine compound with a P-H unit nor the fluoride has been obtained. According to calculated gas-phase structures, solely the unavailable parent phosphine adopts the structure C, and all others prefer structure D (E = O; Fig. 1) (Wrackmeyer, 2014, 233-246).

Scheme 2. Synthesis and major way of decomposition of 2-halogeno-1,3-dioxa-2-phospholanes

All monomer P-organo derivatives 9a–d and even the P-ethoxy- (9e) and P-diethylamino derivative (9f) tend to dimerize within hours or days (Wrackmeyer, 2014, 233-246). Again this is in contrast to A or B (E = O; Fig. 1) which dimerize very slowly or not at all (Dutasta, 1980; Pudovik, 1983). Figure 2 shows the molecular structure of the dimer 10c, as determined by X-ray analysis. In the ten-membered ring the four oxygen atoms are in one plane.
Vol. 1, No. 2 Wrackmeyer et al.: Novel 1,3-dichalcogeno-2-phospholanes...

(mean deviation 1.9 pm), and both phosphorus atoms are shifted out of this plane (88.8 pm, 88.5 pm).

\[\delta^{31}\text{P} \]

\[\text{31} P \text{ NMR spectra show significant deshielding of the } 31 \text{P nuclei in the five-membered rings relative to those in the dimers. This mirrors partly the ring strain together with repulsive effects in the small rings. The structural assignments for the solution-state of monomers and dimers are strongly supported by a linear correlation between calculated [given for the shortcomings of the theoretical approach (van Wüllen, 2000)] and experimental } \delta^{31} \text{P values.}

The annelated carborane skeleton destabilizes monomeric 1,3-dioxa-2-phospholanes. Any gain in kinetical stabilization is more than counterbalanced by steric repulsion between the carborane skeleton and the lone pair of electrons at phosphorus in axial position. According to calculations, solely the hydrogen atom is tolerated in axial position, and all other substituents are forced into the equatorial position to avoid close contacts with the rigid carborane skeleton.
1,3-Dithia- and 1,3-diselena-2-phospholanes with an annelated 1,2-dicarbapcloso-dodecaborane(12) Unit

The best synthetic strategy starts from the silanes 6 (Scheme 4) (Wrackmeyer, 2012; Wrackmeyer, 2014, 1929-1948), although the di-lithium salts 3 (E = S, Se) can also be used (Wrackmeyer, 2007; Wrackmeyer, 2014, *Dalton Trans*). However, the reactions of the silanes 6 with phosphorus halides afford the products in higher purity and much better yield.

**Scheme 4. General synthesis of 1,3-dithia- and 1,3-diselena-2-phospholanes**

![Diagram of Scheme 4]

The phosphorus halides 11 are more stable than their oxygen analogues 7, since the disproportionation products analogous to 8 play a minor role for X = Cl and even less so for X = Br, I. Therefore, the halides can be used to generate the parent compound 13 (R = H) as well as the fluoride 14 (X = F, for E = S) (Scheme 5), at least in reaction solutions in order to measure the most relevant NMR data (Wrackmeyer, 2012; Wrackmeyer, 2014, *Dalton Trans*).

**Scheme 5. Synthesis of the parent compounds 13 and the fluoride 14 for NMR spectroscopy**

![Diagram of Scheme 5]

Figure 3 shows the results of some NMR spectroscopic measurements for 13 (E = S) as an instructive example (Wrackmeyer, 2014, *Dalton Trans*). The NMR data for the corresponding 13 (E = Se) contain even more information, since the $^{77}$Se NMR parameters are also accessible (Wrackmeyer, 2012). Of particular interest is the spin-spin coupling between $^1$H(B-3) and $^1$H(P) (Fig. 2(A)), which can be regarded as a "through-space" coupling. This is not resolved in the case of 13 (E = Se), most likely because of a slightly longer H-H distance. We note reasonably good agreement between calculated and experimental NMR parameters (shown for example in Fig. 2(G, H) for $\delta^{11}$B values). Calculated data were based on the optimized geometry corresponding to C (Fig. 1).
Figure 3. Compound 13 (E = S) (in [D₈]toluene, at 23 °C), showing long range or through-space ¹H–¹H and ³¹P–¹H spin-spin coupling, and assignment of ¹¹B and ¹H(BH) NMR signals. (A) 500.13 MHz ¹H NMR spectrum. (B) 500.13 MHz ¹H[³¹P] NMR spectrum. (C) 202.5 MHz ³¹P NMR spectrum. The isotope-induced chemical shift ¹A[³²/³⁴S][³¹P] (Bjorholm, 1989) is observed. (D) 202.5 MHz ³¹P[¹H] NMR spectrum with ¹H broad-band decoupling. (E) 202.5 MHz ³¹P[¹H] NMR spectrum with selective decoupling of ¹H at 2.55 ppm. (F) 500.13 MHz ¹H[¹¹B] NMR spectrum of 13 with side product (marked by asterisks), assigned by selective ¹H[¹¹B] experiments. (G) 160.5 MHz ¹¹B[¹H] NMR spectrum of 13. (H) Stick diagram of calcd. ¹¹B NMR signals of 13.

The P-organo derivatives 12a–d stay as monomers in solution for a sufficient length of time to measure all important NMR parameters. Any tendency for dimerization is more pronounced for E = S than for E = Se. Thus, for R = Ph, 12d (E = S) dimerizes, whereas 12d (E = Se) does not. By contrast, for R = t-Bu both 12b (E = S, Se) dimerize readily. Also in contrast to 10c (E = O), 12c (E = S, Se) do not dimerize. Similarly, dimers are not formed in the cases of the P–OEt- and P–NEt₂ derivatives 12e, f.

In the cases of 12b with R = t-Bu and 12f with R = NEt₂, calculations predict minima in energy for structure D (E = S, Se; Fig. 1), and the calcd. NMR parameters are in agreement with the experimental data (Wrackmeyer, 2014, Dalton Trans.; Wrackmeyer, 2014, 1929-1948). The delicate balance between the structures C and D (Fig. 1) becomes obvious by comparing the solid-state structure of 12d (E = Se) (Wrackmeyer, 2007), corresponding to D, with that in solution (Wrackmeyer, 2014, 1929-1948), corresponding to C, inferred by NMR spectroscopic data and quantum-chemical analysis (Fig. 4).
**Figure 4.** the solid-state structure of 12d leads to calcd. NMR parameters at drastic variance with experimental data. The latter are almost exactly reproduced by calculations based on the optimized structure shown.

**Figure 5.** Compound 12c (E = Se) (in CD$_2$Cl$_2$, at 23 °C). (A) 125.8 MHz $^{13}$C($^1$H) NMR spectrum. (B) 500.13 MHz $^1$H(PCH$_2$) NMR spectrum. (C) 202.5 MHz $^{31}$P($^1$H) NMR spectrum. The $^{77}$Se satellites for $^1$J($^{77}$Se,$^{31}$P) are marked by $\nabla$. The $^{13}$C satellites for $^2$J($^{31}$P,$^{13}$C) (n = 1, 2) are marked by arrows; isotope-induced chemical shifts $^n\Delta$($^{13}$C($^{31}$P) (n = 1, 2; ± 1 ppb) are given; note that the effect for n = 2 is larger than for n = 1. (D) 95.4 MHz $^{77}$Se NMR spectrum.

Of course, as it is frequently true, we also find that major structural features of the solid state are retained in solution, as shown for both 12c (E = Se) and 15, for which relevant experimental NMR parameters (Fig. 5) are reproduced by calculations (Fig. 6).

The $^{13}$C NMR spectrum of 12c (E = Se) [Fig. 5(A)] shows the doublet for the $^{13}$C$_{carb}$ nuclei, and the signals are further split by isotope-induced chemical shifts $^1\Delta$($^{13}$C) (Wrackmeyer, 2009). An interesting observation concerns
exceptionally large isotope-induced chemical shifts $^2\Delta_{12/13}\text{C}_{\text{carb}}^{(31}\text{P}) = -47 \text{ ppb}$ (Fig. 5(C)). This appears to be a property of the five-membered ring. Isotope-induced chemical shifts $^1\Delta_{12/13}\text{C}^{(31}\text{P})$ are known to cover a substantial range (Tattershall, 1990; Heckmann, 1999), whereas effects $^2\Delta_{12/13}\text{C}^{(31}\text{P})$ are usually regarded as extremely small or negligible. We have observed the large effects $^2\Delta_{12/13}\text{C}_{\text{carb}}^{(31}\text{P})$ for all 1,3-dichalcogeno-2-phospholanes studied here for $E = S, Se, Te$ (Wrackmeyer, 2014, 1929-1948).

**Figure 6.** $^{31}\text{P}$ and $^{77}\text{Se}$ NMR Spectra of 15. Relevant coupling constants have to be extracted by Simulation of the Complex Experimental Spectra using the Spin Systems as shown

There are notable differences between the sulfur and selenium compounds studied here. Thus, the P–Se bonds are more reactive than the P–S bonds, as shown by oxidative additions (Wrackmeyer, 2007). Even the apparently simple addition of selenium to prepare phosphorus selenides (e.g. 16a) turned out to be accompanied by insertion of selenium into the P–Se bonds (17a) (Scheme 6). With the $i$-Pr group ($E = Se; 12a$) a single isomer is formed, whereas two isomers 17d are observed for $R = Ph$, starting from 12d (Wrackmeyer, 2013, 140-147). Again, a single isomer 17c is formed starting from 12c (Wrackmeyer, 2014, 1929-1948). The solid-state structure of 17a could be characterized by X-ray structural analysis (Fig.7), and its formation was conveniently monitored by $^{31}\text{P}$ and $^{77}\text{Se}$ NMR spectroscopy (Fig. 8) (Wrackmeyer, 2013, 140-147).

1,3-Ditellura-2-phospholanes with an annelated 1,2-dicarba-closo-dodecaborane(12) Unit

Since the silane with E = Te analogous to 6 is not accessible so far (Wrackmeyer, 2013, 398-408), the di-lithium salt 3 (E = Te) is used in reactions with phosphorus halides (Scheme 7). Problems are encountered because the nature of 3 depends in an unpredictable way on experimental conditions (Herberhold, 2006; Wrackmeyer, 2013, 398-408). Therefore, the desired products 18 are formed in the presence of numerous side-products, readily shown by $^{31}\text{P}$ and $^{125}\text{Te}$ NMR spectroscopy, which are difficult to separate (Wrackmeyer, 2014, 1929-1948). NMR data indicate that, except of 18e, all others adopt the structure of type C (Fig. 1), even 18b, for which the sulfur and selenium analogues (12b) prefer D (Fig.1). The 1,3-ditellura-2-phospholanes 18 do not dimerize. In contrast to their analogues with E = O, S, Se, compounds 18 are light-sensitive in solution as well as in the solid state.

Scheme 7. Synthesis of 1,3-ditellura-2-phospholanes

Conclusions

In principle, 1,3-dichalcogeno-2-phospholanes with an annelated 1,2-dicarba-closo-dodecaborane(12) unit are accessible taking advantage of the availability of starting materials shown in Scheme 1 and their reactions with phosphorus halides. The annelated rigid three-dimensional carborane skeleton causes repulsive interactions either with the substituent at phosphorus or with the electron density of the lone pair of electrons at phosphorus, depending on the respective structure (C or D; Fig. 1). This destabilizes the five-membered rings, in particular if E–P and E–C_{carb} distances are short, as for E = O, and for many P-organo derivatives, even for E = S and E = Se, dimerization is the way out. All dimers studied so far possess analogous structures, in which the four chalcogen atoms are in one plane leaving room for the complexation or even encapsulating of various cations. It was shown that multinuclear magnetic resonance methods ($^1\text{H}, ^{11}\text{B}, ^{13}\text{C}, ^{31}\text{P}, ^{77}\text{Se}$ and $^{125}\text{Te}$ NMR spectroscopy) together with quantum-chemical analyses were suitable to unravel the solution-state structures which sometimes were found to be at variance with those in the solid state.
